

# Reward Functions for Real-World Pedestrian and Vehicular Intersection Control through Reinforcement Learning

WARWICK  
THE UNIVERSITY OF WARWICK

Alvaro Cabrejas-Egea & Colm Connaughton

# Times of Change in Urban Traffic Control

## Traditional TSCs

- Fixed Time Controllers
- Vehicle Actuated
  - System D
- Adaptive Controllers
  - MOVA
  - SCOOT
- Area Controllers
  - Surtrac

## New Generation of TSCs

- Extra Computing Power
  - GPU-based computation
  - Image analysis
- New Generation of Sensors
  - Vision Based
- New available measurements:
  - Vehicles in Queue
  - Individual Delays
  - Individual Speeds
  - Individual Positions
  - Class of vehicle

# A tale of pedestrians

Plenty of literature on RL for UTC

- Focused on Vehicular Intersections

Specific Requirements for Pedestrians

- Impact on Learning
- Multi-modal optimisation
- Need for more sophisticated data

# Sensing in the Real World

pedes

# Reinforcement Learning for UTC

## Components:

- State estimation (sensing)
- Choosing an action (decision)
- Reward Calculation (feedback)

# Deployment Junction

# Reward Functions

## Quantities

- Queues
- Waiting Time
- Delay
- Average Speed
- Throughput

## Transformation Components

- Instant measurement
- Variation ( $\Delta$ )
- Demand estimation
- Phase-Length Normalisation
- Squared Variables

$$\text{Reward} = a * \text{Reward Vehicles} + b * \text{Reward Pedestrians}$$

# Agents, Training and Testing

- Standard DQN implementation
- State = Occupancy, 12 second buffer at  $\delta=0.6s$
- 2 Hidden layers (sizes 500, 1000), using ReLU.
- Optimized with ADAM,  $\alpha = 10^{-5}$ ;  $\gamma = 0.8$
- Trained 1500 episodes of 30 minutes
- Testing 100 copies of 3 demand levels

## Normal Scenario

## Peak Scenario

## Over-saturated Scenario

### Normal Scenario

### Peak Scenario

### Over-saturated Scenario

# Future Work

- Extension to multiple intersections
- Granular per-entity measurements
- Multi-modal control

# Thank you!
